

FIG. 1: Ratio of propagated NSI to SI atmospheric fluxes at detector level. We set  $\epsilon_{\mu\tau} = -0.05$ , and all other NSI parameters to zero. Dotted (dashed) lines show the regions in which 99% of the DeepCore (IceCube) MC events are contained. *Left panel:* Propagated fluxes of  $\nu_e$  and  $\nu_\tau$  neutrinos and anti-neutrinos. *Right panel:* Propagated fluxes of  $\nu_\mu$  neutrinos and anti-neutrinos

## I. DETECTOR FORMALISM

The neutrino flux at the detector is calculated by propagating the atmospheric neutrino flux [1] through the Earth by solving the Schrödinger equation for varying density. The Earth density profile is taken from the PREM [2]. The baseline for a given trajectory is determined using an average neutrino production height of 15 km and an Earth radius of 6371 km.

The oscillation probability  $P_{\alpha\beta}$  acts as a weight to the atmospheric flux, yielding the propagated flux at detector level for flavor  $\beta$  as

$$\phi_\beta^{\text{det}} = \sum_\alpha P_{\alpha\beta} \phi_\alpha^{\text{atm}}, \quad (1)$$

where we sum over the initial lepton flavors  $\alpha \in \{e, \mu, \bar{e}, \bar{\mu}\}$ . To illustrate the impact of  $\epsilon_{\mu\tau}$  on both probability and flux level, we plot the oscillograms resulting from Eq. 1 in Fig. 1. In the left panel, we have marked the region in which 99% of the DeepCore cascade events originating from  $\nu_e$  and  $\nu_\tau$  fluxes are contained. In the right panel, we show the two regions in which 99% of the IceCube and DeepCore track events originating from  $\nu_\mu$  fluxes are contained. Starting with the  $\nu_\mu$  flux ratio, we see that the only clear signal discernible to the IceCube detector is a flux deficiency of a factor of  $\sim 10^2$  from core-crossing neutrinos within a zenith range of  $\cos(\theta_z^{\text{true}}) > -0.87$ . DeepCore on the other hand, observes multiple fringes of flux surpluses with a factor  $\sim 10$ . The strongest surplus at 20 GeV is very weakly zenith dependent, a stark contrast to the energy-independent but zenith-sensitive IceCube deficiency.

For the fluxes which drives cascades, we have to resort to the DeepCore detector alone. Here we see a somewhat weaker signal, this time a zenith-independent deficiency.

### A. IceCube

The event rate for each bin reads

$$N_{ij} = T \sum_\beta \int_{(\cos \theta_z^r)_i}^{(\cos \theta_z^r)_{i+1}} d \cos \theta_z^r \int_{E_j^r}^{E_{j+1}^r} dE^r \int_0^\pi R(\theta^r, \theta^t) d \cos \theta^t \int_0^\infty \phi_\beta^{\text{det}} A^{\text{eff}} R(E^r, E^t) dE^t, \quad (2)$$

where  $T$  is the live time of the detector, and  $A^{\text{eff}}$  its effective area averaged over the flavors  $\beta$  from [3].  $R(x^r, x^t)$  is a resolution function, which is responsible for the smearing between the reconstructed and true parameters  $x^r$  and  $x^t$ ,

FIG. 2: Relationship between the true and reconstructed muon energy in the IceCube MC sample [4]. Shaded area shows the 99.9th percentile limits predicted by the regressor trained on this set.

respectively. We assume a log-normal distribution, giving it the form

$$R(x^r, x^t) = \frac{1}{\sqrt{2\pi}\sigma_{x^r}x^r} \exp\left[-\frac{(\log x^r - \mu(x^t))^2}{2\sigma_{x^r}^2}\right]. \quad (3)$$

As seen in Fig. 2, the energy reconstruction is biased. To model this relationship between  $E^{true}$  and  $E^{reco}$ , we train a Gaussian process regressor on the dataset [4], from which we can extract a predicted mean and standard deviation for a given  $E^{reco}$ . We then take the  $E^{true}$  points of the 99th percentile of each distribution to obtain the limits of  $E^{true}$  at which to integrate over. We have no angular resolution function since the angle resolution in Icecube for track-like events is less than  $2^\circ$ , making  $\cos(\theta_z^{true})$  coincide with  $\cos(\theta_z^{reco})$  for our study. The data is from the 86 string sterile analysis [5].

## B. DeepCore

In this part, we use the publically available DeepCore data sample [6] which is an updated version of what was used by the IceCube collaboration in a  $\nu_\mu$  disappearance analysis [7].

The detector systematics include ice absorption and scattering, and overall, lateral, and head-on optical efficiencies of the DOMs. They are applied as correction factors using the best-fit points from the DeepCore 2019  $\nu_\tau$  appearance analysis [8].

The data include 14901 track-like events and 26001 cascade-like events, both divided into eight  $\log_{10} E^{reco} \in [0.75, 1.75]$  bins, and eight  $\cos(\theta_z^{reco}) \in [-1, 1]$  bins. Each event has a Monte Carlo weight  $w_{ijk,\beta}$ , from which we can construct the event count as

$$N_{ijk} = C_{ijk} \sum_{\beta} w_{ijk,\beta} \phi_{\beta}^{\det}, \quad (4)$$

where  $C_{k\beta}$  is the correction factor from the detector systematic uncertainty and  $\phi_{\beta}^{\det}$  is defined as Eq. 1. We have now substituted the effect of the Gaussian smearing by treating the reconstructed and true quantities as a migration matrix.

The oscillation parameters used on our DeepCore simulations are from the best-fit in the global analysis in [9]:  $\theta_{12} = 33.44^\circ$ ,  $\theta_{13} = 8.57^\circ$ ,  $\Delta m_{21}^2 = 7.42 \text{ eV}^2$ , and we marginalize over  $\Delta m_{31}^2$  and  $\theta_{23}$ .

We plot the event pull  $(N_{NSI} - N_{SI})/\sqrt{N_{SI}}$  where  $N_{SI}$  ( $N_{NSI}$ ) are the numbers of expected events assuming standard (non-standard) interactions in Fig. 3b. This gives the normalized difference in the number of expected events at the detector, and illustrates the expected sensitivity of DeepCore for the NSI parameters.

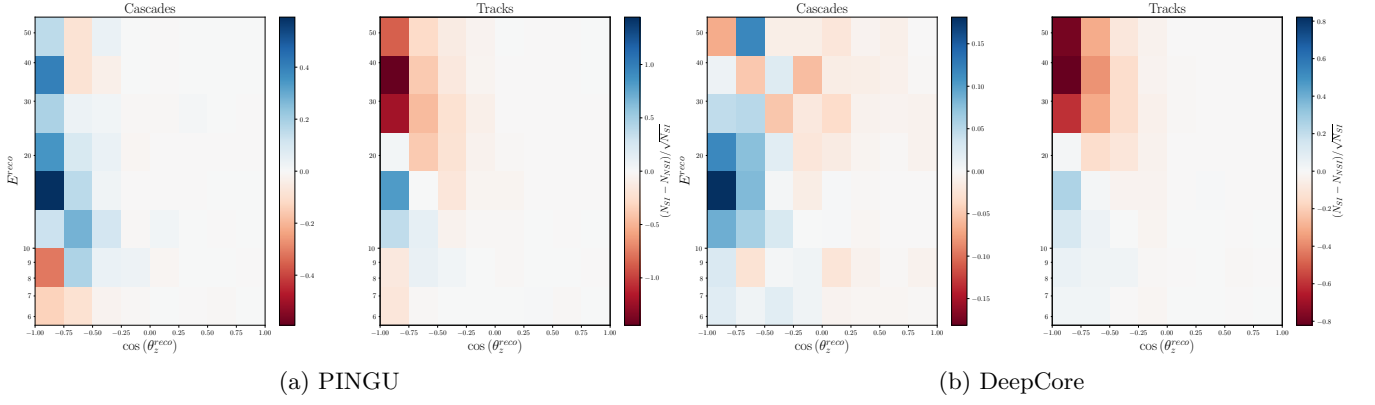

FIG. 3: Expected pulls of predicted event numbers for PINGU and DeepCore after 3 years. We compare the NSI event count with  $\epsilon_{\mu\tau} = -0.05$  to the standard interaction count

### C. PINGU

The methodology behind the PINGU simulations are the same as with our DeepCore study IB. We use the public MC [10], which allows us to construct the event count as in Eq. 4. However, since no detector systematics is yet modelled for PINGU, the correction factors  $C_{ijk}$  are all unity. As with the DeepCore data, the PINGU MC is divided into eight  $\log_{10} E^{reco} \in [0.75, 1.75]$  bins, and eight  $\cos(\theta_z^{reco}) \in [-1, 1]$  bins for both track- and cascade-like events. Just as with DeepCore, we plot the events pulls for cascades and tracks in Fig. 3a. We generate ‘data’ by predicting the event rates at PINGU with the following best-fit parameters from [9], except for the CP-violating phase which is set to zero for simplicity.

$$\begin{aligned} \Delta m_{21}^2 &= 7.42 \times 10^{-5} \text{ eV}^2, \quad \Delta m_{31}^2 = 2.517 \times 10^{-3} \text{ eV}^2, \\ \theta_{12} &= 33.44^\circ, \quad \theta_{13} = 8.57^\circ, \quad \theta_{23} = 49.2^\circ, \quad \delta_{CP} = 0. \end{aligned} \quad (5)$$

## II. RESULTS

### A. Methodology

For our analyses, we define our  $\chi^2$  as

$$\chi^2(\hat{\theta}, \alpha, \beta, \kappa) = \sum_{ijk} \frac{(N^{\text{th}} - N^{\text{data}})_{ijk}^2}{(\sigma_{ijk}^{\text{data}})^2 + (\sigma_{ijk}^{\text{syst}})^2} + \frac{(1 - \alpha)^2}{\sigma_\alpha^2} + \frac{\beta^2}{\sigma_\beta^2} \quad (6)$$

where we minimize over the model parameters  $\hat{\theta} \in \{\Delta m_{31}^2, \theta_{23}, \epsilon\}$ , the penalty terms  $\alpha$  and  $\beta$ , and the free parameter  $\kappa$ .  $N_{ijk}^{\text{th}}$  is the expected number of events from theory, and  $N_{ijk}^{\text{data}}$  is the observed number of events in that bin. We set  $\sigma_\alpha = 0.25$  as the atmospheric flux normalization error, and  $\sigma_\beta = 0.04$  as the zenith angle slope error [1]. The observed event number has an associated Poissonian uncertainty  $\sigma_{ijk}^{\text{data}} = \sqrt{N_{ijk}^{\text{data}}}$ .

For IceCube, the event count takes the form

$$N_{ijk}^{\text{th}} = \alpha [1 + \beta(0.5 + \cos(\theta_z^{reco})_i)] N_{ijk}(\hat{\theta}), \quad (7)$$

with  $N_{ijk}(\hat{\theta})$  from Eq. 2. Here, we allow the event distribution to rotate around the median zenith angle of  $\cos(\theta_z^{reco}) = -0.5$ .

For DeepCore and PINGU, and the event count takes the form

$$N_{ijk}^{\text{th}} = \alpha [1 + \beta \cos(\theta_z^{reco})_i] N_{ijk}(\hat{\theta}) + \kappa N_{ijk}^{\mu atm}, \quad (8)$$

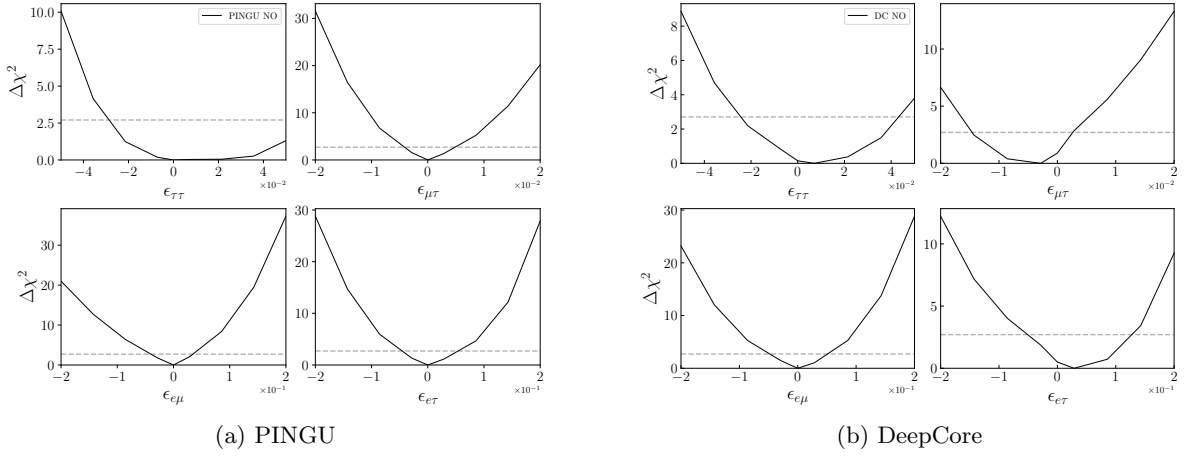

FIG. 4: Minimization of the  $\Delta\chi^2$  defined in Eq. 6 after three years of data.  $\Delta m_{31}^2$  and  $\theta_{23}$  have been marginalized out, and all other NSI parameters other than the one shown in each panel are fixed to zero.

Parameter	90% CL	Best fit		
		$\Delta m_{31}^2$	$\theta_{23}$	$\epsilon$
DeepCore				
$\epsilon_{\tau\tau}$	-0.028, 0.044	2.435	47.84	0.0125
$\epsilon_{\mu\tau}$	-0.015, 0.0050	2.435	43.97	-0.005
$\epsilon_{e\mu}$	-0.068, 0.070	2.435	43.97	0
$\epsilon_{e\tau}$	-0.072, 0.14	2.435	43.97	0.05
PINGU				
$\epsilon_{\tau\tau}$	-0.036, -	2.517	49.2	0
$\epsilon_{\mu\tau}$	-0.0076, 0.0085	2.517	49.2	0
$\epsilon_{e\mu}$	-0.060, 0.055	2.517	49.2	0
$\epsilon_{e\tau}$	-0.065, 0.072	2.517	49.2	0

TABLE I: DeepCore and PINGU results from the  $\Delta\chi^2$  in Fig. 4. Best fit points for  $\Delta m_{31}^2$  and  $\theta_{23}$  are given in units of  $10^{-3}\text{eV}^2$  and degrees, respectively.

with  $N_{ijk}(\hat{\theta})$  from Eq. 4.  $N_{ijk}^{\mu atm}$  is the muon background, which is left to float freely in the DeepCore analysis. The background at PINGU can be considered negligible to first order [10], and we thus put  $\kappa = 0$  when calculating the PINGU  $\chi^2$ . Since the median zenith is  $\cos(\theta_z^{reco}) = 0$  for DeepCore and PINGU, we allow the event count to rotate around zero. For IceCube, we set  $\sigma_{ijk}^{\text{syst}} = f\sqrt{N_{ijk}^{\text{data}}}$ . For DeepCore, we use the provided systematic error distribution which accounts for both uncertainties in the finite MC statistics and in the data-driven muon background estimate [6].

## B. Constraining the NSI parameters

First, we set all standard oscillation parameters to their current best-fit values of Eq. 5, except for  $\Delta m_{31}^2$  and  $\theta_{23}$ , which we marginalize over their  $3\sigma$  ranges of  $2.435 \times 10^{-3}$  to  $2.598 \times 10^{-3} \text{eV}^2$  and  $40.1$  to  $51.7^\circ$  respectively. After the oscillation parameters have been marginalized out, we plot  $\Delta\chi^2$  for each of the four NSI parameters in Fig. 4. We record the confidence levels and best-fit points in Table. I.

Comparing the PINGU results in Fig. 4a and the DeepCore results in Fig. 4b, we note that the best-fit for each NSI parameter for the PINGU experiment is expected to be zero. This is because the ‘data’ we generated during the PINGU simulations assumes no NSI since they have yet to be observed in nature. This introduces a non-NSI bias in our joint analysis, since PINGU has stronger statistics than DeepCore, and will thus pull the joint  $\chi^2$  towards  $\epsilon = 0$ .

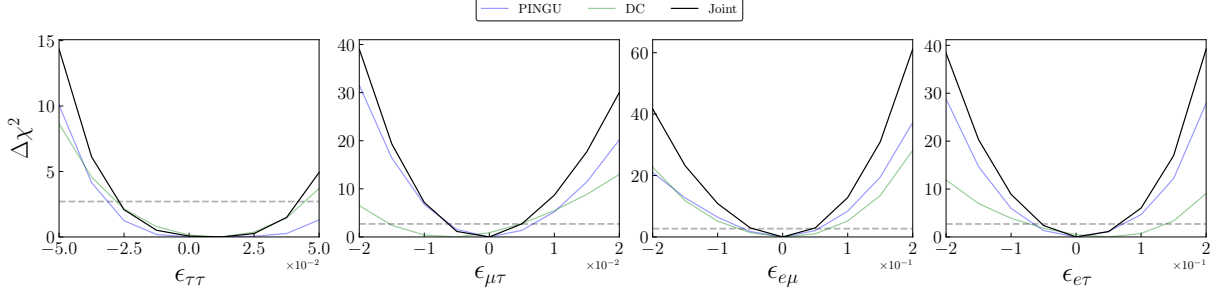

FIG. 5: Expected joint  $\Delta\chi^2$  from Eq. 9 for normal ordering.

Parameter	90% CL	Best fit		
		$\Delta m_{31}^2$	$\theta_{23}$	$\epsilon$
$\epsilon_{\tau\tau}$	-0.029, 0.0473	2.489	47.84	0.0125
$\epsilon_{\mu\tau}$	-0.0063, 0.0050	2.489	47.84	0
$\epsilon_{e\mu}$	-0.046, 0.046	2.489	47.84	0
$\epsilon_{e\tau}$	-0.057, 0.028	2.489	47.84	0

TABLE II: Joint results from  $\chi_{\text{joint}}^2$  defined in Eq. 9. Best fit points for  $\Delta m_{31}^2$  and  $\theta_{23}$  are given in units of  $10^{-3}\text{eV}^2$  and degrees, respectively

For the joint analysis, we follow the parameter goodness-of-fit prescription [11] and construct the joint  $\chi^2$  as

$$\chi_{\text{joint}}^2 = \chi_{\text{IC}}^2 + \chi_{\text{DC}}^2 + \chi_{\text{P}}^2 - \chi_{\text{IC},\text{min}}^2 - \chi_{\text{DC},\text{min}}^2 - \chi_{\text{P},\text{min}}^2 \quad (9)$$

with test statistic  $\chi_{\text{joint},\text{min}}^2$ . The results are shown in Fig. 5 and summarized in Table II.
